Build Plan: 6-Person Split

Oct 28, 2026 · @Ellie

Six owners, one per part of the architecture, working in parallel against shared schemas agreed in the first hour.

Shared contracts (everyone, first hour)

Agree these four JSON shapes before anyone codes, so all six can build against mocks and plug together later.

Contract	Owner	Holds
Playbook	Person 2	Process name, customer type (PF/PJ), required documents with validity rules, cross-checks, screening steps
Case file	Person 3	Case id, customer type, uploaded documents, each with type, owner and extracted fields
Extracted field	Person 3	Value, confidence, source location (document, page, bounding box) for evidence links
Flag	Person 1	Severity, rule broken (from the playbook), evidence locations, suggested fix message for the client

- [ ] Pick the stack and LLM provider, create the repo with folders per owner
- [ ] Write the four schemas as JSON examples in the repo
- [ ] Agree one demo storyline: one PF case, one PJ case, one process taught live

Person 1: Tech lead, orchestration and guardrails

Owns the agent that runs the pipeline end to end and the audit log (diagram stages 3, 5 and guardrails).

- [ ] Agent orchestrator: loads a playbook, runs Classify → Extract → Validate → Cross-check → Tamper → Screening → Risk draft as tools
- [ ] PF and PJ tracks: for PJ, run the natural-person flow for every UBO and signatory
- [ ] Fix-request loop: failed checks become client messages sent back to the intake agent
- [ ] Audit log: every tool call, input, output and timestamp stored per case

- [ ] Guardrails: least-privilege tools, document text treated as untrusted input, no tool that makes a final decision
- [ ] Integration owner: merges modules, keeps the main branch demo-ready

Person 2: Playbook builder (headline differentiator)

Owns turning a procedure document into a playbook (diagram stage 1).

- [ ] Write three short fictional procedures: KYC persoane fizice, KYB persoane juridice, popriri (the live-taught one)
- [ ] Builder: procedure Word/PDF → LLM → playbook JSON matching the contract
- [ ] Validator: reject playbooks with unknown document types or checks the pipeline can't run
- [ ] Review screen data: show the generated rules next to the procedure sentences they came from
- [ ] Rehearse the live moment: upload popriri procedure, playbook ready in under 2 minutes

Person 3: Document pipeline

Owns Classify, Extract, Validate and Cross-check (diagram stage 3, first row).

- [ ] Classify: document type and which person it belongs to
- [ ] Extract: fields with source location (page + bounding box) for evidence links
- [ ] Validate: expiry dates, document age (e.g. payslip within 30 days), missing required documents
- [ ] Cross-check: name, CNP, address, income vs. deposits; registry extract vs. UBO declaration for PJ
- [ ] Every result emits flags in the shared Flag format, citing the playbook rule

Person 4: Tamper detection, screening and risk draft

Owns the second row of diagram stage 3.

- [ ] Tamper detection: PDF metadata (creator app, edit dates), font inconsistencies, statement totals that don't add up
- [ ] Mock registries as tools: ONRC company lookup by CUI, sanctions/PEP list with fuzzy name matching, adverse media stub
- [ ] Ownership graph for PJ: shareholders → UBOs, compared with the declared beneficiar real

- [ ] Risk draft: risk level with reasons by country, occupation, CAEN code; never a decision

Person 5: Synthetic data, then pitch

Owns the fictional client files the whole demo runs on, then the story.

- [ ] 3–4 PF case files: ID, selfie, proof of address, payslips, bank statements
- [ ] 2–3 PJ case files: certificat constatator, act constitutiv, UBO declaration, administrators' IDs
- [ ] Plant errors on purpose: expired ID, address mismatch, edited payslip, PEP hit, UBO not matching the registry, missing document
- [ ] One clean case per type, to show auto-clear
- [ ] Ground-truth sheet: every planted error, so the team can measure what the agent catches
- [ ] Pitch deck and demo script, with the time-saved number from the test run

Person 6: Frontend

Owns the two screens people see (diagram stages 2 and 5).

- [ ] Client upload screen with the live intake agent: checks each document as it lands and says what to fix
- [ ] Analyst review screen: case summary, risk draft, flags list
- [ ] Evidence links: clicking a flag opens the document with the exact spot highlighted and the rule shown
- [ ] Decision buttons (approve, reject, request documents), human only
- [ ] Audit log view per case
- [ ] Playbook review screen for Person 2's live demo moment

Milestones

Four checkpoints, set by phase rather than clock time; map them onto your hackathon hours.

1. **Contracts locked:** schemas in the repo, everyone builds against mock data.
2. **First end-to-end run:** one PF case through every stage with stubbed modules, flags visible in the analyst screen.
3. **Feature complete:** real modules swapped in, PJ track working, popriri playbook generated from its procedure.

4. **Demo freeze:** no new features; run the ground-truth test, record the numbers, rehearse twice.

Demo script (about 4 minutes)

1. Client uploads a PF file; the intake agent catches the expired ID and an old payslip live.
2. Analyst screen: tampered payslip and address mismatch flagged, click opens the exact spot.
3. PJ case: UBO declaration doesn't match the registry; ownership graph shows why.
4. Upload the popriri procedure; a new process works minutes later.
5. Close on the numbers: errors caught out of planted errors, minutes per file vs. manual.
